PREDATION, PARTICULARLY BY SCULPINS, ON SALMON FRY IN

FRESH WATERS OF WASHINGTON

By

BENJAMIN G. PATTEN, Fishery Research Biologist

National Marine Fisheries Service Northwest Fisheries Center 2725 Montlake Boulevard East Seattle, WA 98102

ABSTRACT

Stomach contents of 41 species of fish collected in one lake and ll streams were examined to determine species that were predaceous on wild and cultured Pacific salmon, <u>Oncorhynchus</u> spp., fry. The only species with salmon in their stomachs were: sculpins, <u>Cottus</u> spp., coho salmon, <u>O. kisutch</u>, chinook salmon, <u>O. tshawytscha</u>, rainbow trout, <u>Salmo</u> <u>gairdneri</u>, and cutthroat trout, <u>S. clarki</u>. Presented are data on the number of salmon in the stomachs of the predators and on body lengths of the predator species.

INTRODUCTION

Pacific salmon, <u>Oncorhynchus</u> spp., are of great value to sport and commercial fisheries of the Pacific Northwest. Effort to increase production of salmon in Washington is mainly by artificial propagation to supplement natural production and by regulatory measures to protect brood stocks. Control or alteration of some biological features of the environment, however, can also help to increase the numbers of natural and artificially produced salmon. Control of populations of predators, for example, might benefit some stocks of salmon.

Information is needed to determine whether control of some populations of fish that prey on salmon during the salmon's juvenile life (particularly when the salmon are recently hatched) in natal river systems (when and where mortality is highest and control measures are relatively easy to implement) would help to increase the numbers of salmon. I report on this by listing data on predation in some Washington river systems. This report is essentially on predation of wild salmon in 10 streams; however, I also present data on predation of cultured salmon in a lake and two streams. Of the predatory species, sculpins, Cottus spp., were the most abundant and received my greatest attention. Sculpins are widely distributed and known to be predaceous on young salmon (Hunter, 1959; Sheridan and Meehan, $1962\frac{1}{}$; Patten, 1962, 1971), eaters

^{1/} Sheridan, W. L., and W. R. Meehan. 1962. Rehabilitation of Big Kitoi outlet stream, Afognak Island, Alaska. Alaska Dep. Fish Game, Div. Biol. Res., Juneau, Inform. Leafl. 11, 13 p. (Processed.)

of salmon eggs (Mattson, Rowland, and Hobart, 1964^{2/}; McLarney, 1964; Phillips and Claire, 1966), and are probably eaters of the same foods as salmon. Additonal information on predation by sculpin on salmon of hatchery origin has been reported by Patten (1971).

METHODS OF COLLECTING AND PROCESSING

Fish were sampled from 11 streams and one lake in 1961 and 1962. They were collected from the streams with the Bureau of Commercial Fisheries Type IV electric fish shocker (Patten and Gillaspie, 1966) during daylight and from the lake with a gill-net set on the bottom overnight. All captured fish less than 55 to 60 mm in total length were released because preliminary study had indicated that fish less than 55 to 60 mm long were not feeding on the young salmon. Sample size varied with duration of fishing effort, fish density, stream, and weather conditions.

All fish taken for study were preserved in Formalin in the field and examined later in the laboratory. In the laboratory each fish was identified and measured (snout to fork of tail in mm, or to tip of tail for sculpins) and the ingested salmon counted. Small numbers of salmon fry were collected from each stream and they were examined to determine the species of prey present.

The taxonomic characters of riffle sculpin, C. gulosus, and reticulate

sculpin, <u>C. perplexus</u>, have not been clearly distinguished. I consider specimens of these two species in my collections to be reticulate sculpin, although the data of Reimers and Bond (1967) show overlapping geographic distributions of these two species in some of the areas where I collected fish. Locations of sampling sites in streams presented in the text and tables are given in kilometers (km) from mouth of stream.

PREDATION BY LOCATION

Data on predation in a lake and in two streams stocked with cultured salmon are presented first, followed by data on predation in 10 streams containing wild salmon.

On Cultured Salmon

Lake Wenatchee. -- Sockeye salmon, O. <u>nerka</u>, were released from 27 September to 16 October 1961 into Lake Wenatchee, Chelan County. Sculpins were collected before and after this. The numbers of salmon eaten by prickly sculpin, <u>C. asper</u>, are shown in Table 1 and length frequencies of prickly sculpin are shown in Figure 1.

<u>Abernathy Creek.</u> --Abernathy Creek in Cowlitz County was sampled in 1961 and 1962 to determine predation on fry of chum salmon, <u>O. keta</u>, released from an artificial spawning channel at km 6.4.

In 1961, about 2,000 chum salmon were collected from an artificial spawning channel and released into the outlet channel. Predatory fish were collected at the mouth of the outlet channel about 2 hr after this release. On 1 and 25 May 1962, two collections of predators were made the day after 8,437 and 33,155 chum salmon fry, respectively, had emigrated into the outlet channel at night. Numbers of salmon eaten by

^{2/} Mattson, C. R., R. G. Rowland, and R. A. Hobart. 1964. Chum salmon studies in southeastern Alaska, 1963. U.S. Fish Vildl. Serv. Bur. Commer. Fish., Biol. Lab., Auke Bay, Alaska, MS Rep. 64-8, 22 p. (Processed.)

sampled fish are given in Table 2; length frequencies of predators are shown in Figures 1 to 6.

Vance Creek. -- Vance Creek in Mason County was sampled at the site of a release of hatchery reared fall chinook salmon fry, O. tshawytscha. Personnel of the Washington Department of Fisheries released an estimated 403, 750 fall chinook salmon fry (1, 400/kg) into Vance Creek about 100 m above its confluence with the Skokomish River on 14 March 1962. I collected fish from this section of the stream on 16 March. Fall chinook salmon fry were extremely abundant throughout the stream and most were found hiding under rocks. Numbers of salmon eaten by predators taken in Vance Creek are shown in Table 3; length frequencies of predatory species are shown in Figures 1 to 5.

On Wild Salmon

Piscivorous fish were sampled in 10 streams when salmon fry were emerging from the gravel or were abundant in streams. The salmon fry as prey species, which I collected, were coho, O. <u>kisutch</u>, chinook, and chum salmon; I observed few chum salmon fry, however, in the streams where large numbers of adults had spawned the previous fall.

Abernathy Creek. --A collection of fish was taken from Abernathy Creek 1.6 km above its confluence with the Columbia River on 9 April 1962. Coho salmon fry were abundant in the shallows at the time of sampling. Numbers of salmon fry eaten by the collected fish are shown in Table 4; length frequencies are shown in Figures 1 to 5.

<u>Glen Cove Creek.</u> --Chum and coho salmon fry were present in the lower part of this small creek in Pierce County which empties into lower Puget Sound. Data on predation of salmon fry by the collected fish are shown in Table 5; length frequencies are shown in Figures 1, 2, and 5.

Grays River. --Grays River was sampled in Wahkiakum County, about 3 km above the influence of tides. Sampling was limited to areas of cover inside the channels where coho salmon fry were most abundant. Data on predation of salmon fry by the collected fishes are shown in Table 6; length frequencies are shown in Figures 3, 5, and 6.

<u>Green River.</u> --A sample of fish was taken from Green River in King County, adjacent to Soos Creek and from the mouth of Soos Creek. Coho salmon fry were few, whereas chinook salmon fry were abundant. Data on predation of salmon fry by the collected fishes are shown in Table 7; length frequencies are shown in Figures 2, 5, and 6.

Hamilton Creek. --A collection of fish was made in this Skamania County creek, 2 km from the mouth at a time of flooding and high turbidity. Coho salmon fry were dispersed through the flooded stream channel. Data on predation of salmon fry by the collected fish are shown in Table 8; length frequencies are shown in Figures 1, 3, 5, and 6.

<u>Newaukum Creek.</u> --Newaukum Creek, a tributary of Green River in southern King County, was sampled in the spring of 1961 and 1962 at various times and locations. Abundance of coho salmon fry within an area of the stream was in proportion to the amount of cover and, although fall chinook salmon were observed to spawn in the lower kilometers, fry of this species were not collected. Data on predation of salmon fry by the collected fish are shown in Table 9; length frequencies are shown in Figures 1 to 3 and in 5 and 6.

Raging River. -- A collection of fish was taken from the Raging River in King

County, 3 km above its confluence with the Snoqualmie River. At the time of sampling, coho salmon fry were abundant in the shallows. The number of salmon fry eaten by the collected fish are shown in Table 10; length frequencies are shown in Figures 3 and 6.

Rocky Creek. --Rocky Creek, a tributary to lower Puget Sound in Pierce County, was sampled on four occasions from the tidal zone 0.2 km below the highway (Wash., 302) bridge to 1 km upstream of the bridge. Coho, chinook, and fall and winter chum salmon spawn in Rocky Creek; however, the only salmon fry observed were coho and a few chum. The number of salmon fry eaten by the collected fish are shown in Table 11; length frequencies are shown in Figures 1 to 5.

Yakima River. -- The Yakima River was sampled March-June 1961 in Kittitas County from Cle Elum (km 257) to below Easton Dam (km 286). Identification of coho and chinook yearlings in this collection was difficult; therefore, these fish are combined. The density of coho and chinook fry varied from few to abundant depending upon the amount of cover, and their density decreased with distance downstream from km 286. Salmon fry eaten by predators were treated as one group because species of some salmon taken from the predators' stomachs could not be determined. Numbers of salmon eaten by the collected fish are shown in Table 12; length frequencies are shown in Figures 2 and 3 and in 6 to 8.

Unnamed Creek. --Predators on salmon fry were collected in the 100 m of the creek above its confluence with the Skokomish River in Mason County. Coho fry were more abundant than chinook and chum. Numbers of salmon fry eaten by the collected fish are shown in Table 13; length frequencies are shown in Figure 1 and in Figures 3 to 5.

ACKNOWLEDGMENTS

This study was carried out under the National Marine Fisheries Service Columbia River Operation Studies Program. I wish to express my appreciation to R. J. Gerke and, especially, to D. F. Tufts for their assistance in collecting and examining fish.
